Abstract

Reduced lung function predicts mortality and is key to the diagnosis of COPD. In a genome-wide association study in 400,102 individuals of European ancestry, we define 279 lung function signals, 139 of which are new. In combination, these variants strongly predict COPD in independent patient populations. Furthermore, the combined effect of these variants showed generalisability across smokers and never-smokers, and across ancestral groups. We highlight biological pathways, known and potential drug targets for COPD and, in phenome-wide association studies, autoimmune-related and other pleiotropic effects of lung function associated variants. This new genetic evidence has potential to improve future preventive and therapeutic strategies for COPD.

Introduction

Impaired lung function is predictive of mortality¹ and is the key diagnostic criterion for chronic obstructive pulmonary disease (COPD). Globally, COPD accounted for 2.9 million deaths in 2016², being one of the key causes of both Years of Life Lost and Years Lived with Disability worldwide³. Determinants of maximally attained lung function and of lung function decline can influence the risk of developing COPD. Tobacco smoking is the single largest risk factor for COPD, although other environmental exposures and genetic makeup are important⁴.⁵. Genetic variants associated with lung function and COPD susceptibility can provide aetiological insights, assisting with risk prediction, as well as drug target identification and validation⁶. Whilst there has been considerable progress in identifying genetic markers associated with lung function and risk of COPD⁴,7·19 seeking a high yield of associated genetic variants is key to progressing knowledge because: (i) implication of multiple molecules in each pathway will be needed to build an accurate picture of the pathways underpinning development of COPD; (ii) not all proteins identified will be druggable and; (iii) combining information across multiple variants can improve prediction of disease susceptibility.

Through new detailed quality control and analyses of spirometric measures of lung function in UK Biobank and expansion of the SpiroMeta Consortium, we undertook the largest genome-wide association study of lung function performed to date. Our study entailed a near seven-fold increase in sample size over previous studies of similar ancestry to address the following aims: (i) to generate a high yield of genetic markers associated with lung function; (ii) to confirm and fine-map previously reported lung function signals; (iii) to investigate the putative causal genes and biological pathways through which lung function associated variants act, and their wider pleiotropic effects on other traits; and (iv) to generate a weighted genetic risk score for lung function and test its association with COPD susceptibility in individuals of European and other ancestries.

Results

139 new signals for lung function

We increased the sample size available for the study of quantitative measures of lung function in UK
Biobank by refining the quality control of spirometry based on recommendations of the UK Biobank
Outcomes Adjudication Working Group (Supplementary Note). Genome-wide association analyses
of forced expired volume in 1 second (FEV₁), forced vital capacity (FVC) and FEV₁/FVC were then
undertaken in 321,047 individuals in UK Biobank (Supplementary Table 1) and in 79,055 individuals
from the SpiroMeta Consortium (Supplementary Tables 2 and 3). A linear mixed model approach
implemented in BOLT-LMM²⁰ was used for UK Biobank to account for relatedness and fine-scale

- 217 population structure (Online Methods). A total of 19,871,028 autosomal variants imputed in both
- 218 UK Biobank and SpiroMeta were analysed. Peak expiratory flow (PEF) was also analysed genome-
- 219 wide in UK Biobank and up to 24,218 samples from SpiroMeta. GWAS results in UK Biobank were
- adjusted for the intercept of LD score regression²¹, but SpiroMeta and the meta-analysis were not as
- intercepts were close to 1.00 (Online Methods). All individuals included in the genome-wide
- analyses were of European ancestry (Supplementary Figure 1 and Supplementary Note).
- 223 To maximise statistical power for discovery of new (previously unreported) signals, whilst
- 224 maintaining stringent significance thresholds to minimise reporting of false positives, we adopted a
- study design incorporating both two-stage and one-stage approaches (Figure 1). In the two-stage
- analysis, 99 new distinct signals, defined using conditional analyses²², were associated with one or
- more traits at P<5×10⁻⁹ in UK Biobank and showed association (P<10⁻³) with a consistent direction of
- 228 effect in SpiroMeta ("Tier 1" signals, Supplementary Figure 2; Supplementary Table 4). In the one-
- stage analysis, we meta-analysed UK Biobank and SpiroMeta (up to 400,102 individuals) and 40
- additional new distinct signals associated with one or more lung function traits reaching P<5×10⁻⁹
- 231 (see ²³) were identified (**Supplementary Figure 2, Supplementary Table 4**) that were also associated
- with P<10⁻³ separately in UK Biobank and in SpiroMeta, with consistent direction of effect ("Tier 2"
- 233 signals). An additional 323 autosomal signals were significantly associated with one or more lung
- function traits in the meta-analysis of UK Biobank and SpiroMeta (P<5×10⁻⁹) and reached P<10⁻³ for
- association in only one of UK Biobank or SpiroMeta ("Tier 3" signals, **Supplementary Table 5**).
- 236 Analysis of association of FEV₁, FVC and FEV₁/FVC with 240,417 chromosome X variants in 359,226
- 237 individuals (321,027 UK Biobank and 38,199 SpiroMeta¹⁵) gave an additional 5 Tier 3 signals. Only
- 238 the 139 signals meeting Tier 1 and Tier 2 criteria were followed up further. The strength and
- direction of association of the sentinel variant (the variant in each signal with the lowest P value) for
- these 139 new signals across all 4 lung function traits are shown in Figure 2. Of the 139 signals, 131
- were associated with at least two lung function traits at P<10⁻³, eight signals were unique to
- 242 FEV₁/FVC and no signals were unique to FEV₁, FVC or PEF at this threshold.
- 243 We assessed whether any of these 139 signals associated with lung function could be driven via an
- underlying association with smoking behaviour (Online Methods). Only rs193686 (in an intron of
- 245 MET, Supplementary Table 6) was associated with smoking behaviour. Therefore, we tested for
- association between this variant and lung function in never smokers (n=173,658). Whilst rs193686
- was associated with smoking initiation (P=9.18×10⁻⁶), the allele associated with smoking initiation
- was associated with increased lung function in never smokers (FEV₁/FVC P=5.28×10⁻¹⁰,
- **Supplementary Table 7**). Therefore, this signal was retained for further analysis.

250 A total of 279 signals of association for lung function

- Of 157 previously published signals of association with lung function and COPD^{3,6-18}, 142 were
- associated at P<10⁻⁵ in UK Biobank (**Online Methods, Supplementary Figure 3, Supplementary Table**
- 253 8). Two sentinel variants (rs1689510 and rs11134789) were associated with smoking initiation
- 254 (Supplementary Table 6), but were also associated with lung function in never smokers
- 255 (Supplementary Table 7). SNP rs17486278 at CHRNA5 and rs11667314 near CYP2A6 were each
- associated with cigarettes per day (Supplementary Table 6); neither were significantly associated
- with lung function among never smokers and so were excluded from further analysis. This brings the
- total number of distinct signals of association with lung function to 279 (Supplementary Table 9).
- None of these variants showed interaction with ever-smoking status (P>1.8×10⁻⁴, **Online Methods**,

- 260 **Supplementary Table 7**). Using the effect estimates, allele frequencies and assuming a total
- heritability of 40%^{24,25} (**Online Methods**), we calculated that the 140 previously reported lung
- function signals showing association in this study (UK Biobank P<10⁻⁵) explained 5.0%, 3.4%, 9.2%
- and 4.5% of the estimated heritability of FEV₁, FVC, FEV₁/FVC and PEF, respectively. The 139 new
- signals reported here, explain an additional 4.3%, 3.3%, 3.9% and 3.3% of the estimated heritability,
- 265 respectively.

266 Identification of putative causal genes

- 267 Bayesian refinement was undertaken for each signal to identify the set of variants that were 99%
- 268 likely to contain the underlying causal variant (assuming the causal variant has been analysed). The
- 269 results from the meta-analysis of UK Biobank and SpiroMeta were used to define the 99% credible
- sets (Online Methods, Supplementary Table 10, Supplementary File-Region Plots).
- 271 To identify putative causal genes for each signal, we identified deleterious variants and variants
- associated with gene expression (eQTLs) or protein levels (pQTLs) within each 99% credible set for all
- 273 new and previously reported signals outside the HLA region (Online Methods).
- 274 There were 25 SNPs, located in 22 unique genes, which were annotated as potentially deleterious
- 275 (Online Methods, Supplementary Table 11). Amongst our new signals, there were 10 variants
- annotated as deleterious in 9 different genes: DOCK9 (rs117633128), CEP72 (rs12522955), BCHE
- 277 (rs1799807), DST (rs11756977), KIAA0753 (rs2304977, rs9889363), LRRC45 (rs72861736), BTC
- 278 (rs11938093), C2orf54 (rs6709469) and IER5L (rs184457). Of these, the missense variant in BCHE
- 279 (rs1799807) had the highest posterior probability (0.996) in its respective credible set, was low
- 280 frequency (MAF=1.95%) and resulted in an amino acid change from aspartic acid (D) to glycine (G),
- 281 known to affect the function of the encoded butyrylcholinesterase enzyme by altering substrate
- binding²⁶. The two common missense variants in *KIAA0753* were within the credible set of new
- signal rs4796334. KIAA0753, CEP72 and LRRC45 all encode proteins with a role in ciliogenesis or cilia
- maintenance²⁷⁻³¹, and all are highly expressed in the airway epithelium³².
- Variants in the 99% credible sets were queried in three eQTL resources to identify associations with
- gene expression in lung³³⁻³⁵ (sample size n=1,111; **Supplementary Table 12**), blood³⁶ (n=4,896) and a
- subset of GTEx³⁷ tissues (max n=388, **Online Methods**). The tissues included from GTEx were lung
- and blood, plus nine tissues known to contain smooth muscle (Online Methods). The latter were
- 289 chosen based on previous reports of enrichment of lung function GWAS signals in smooth muscle-
- containing tissues^{18,38}. We identified 88 genes, implicated by 58 of the 279 signals, for which the
- 291 most significant SNP associated with expression of that gene in the respective eQTL resource was
- within one of the 99% credible sets (Supplementary Table 13).
- 293 We checked credible set variants for association with protein levels in a pQTL study³⁹ comprising SNP
- associations for 3,600 plasma proteins (Online Methods). We found 5 proteins with a sentinel pQTL
- contained within our lung function credible set: ECM1, THBS4, NPNT, C1QTNF5 and SCARF2
- 296 (Supplementary Table 14).
- 297 In total, 107 putative causal genes were identified (**Table 1**), amongst which, we highlight 75 for the
- 298 first time as putative causal genes for lung function (43 implicated by a new signal and 32 newly
- 299 implicated by a previous signal¹⁸).

Pathway analysis

300

311

- We tested whether these 107 putative causal genes were enriched in gene sets and biological
- 302 pathways (Online Methods), finding an enrichment of genes in elastic fibre and extracellular matrix
- organisation pathways, and a number of gene ontologies including gene sets relating to the
- 304 cytoskeleton and processes involved in ciliogenesis (Supplementary Table 15). Whilst the
- enrichment in elastic fibre-related pathways is consistent with our previous study¹⁸, enrichment in
- these pathways was further supported in this analysis by two new genes, ITGAV (at a new signal) and
- 307 GDF5 (a newly implicated gene for a previously reported signal), and by strengthened eQTL evidence
- for TGFB2 and MFAP2 at two previously reported signals. The presence of TGFB2, GDF5 and SMAD3
- 309 in our list of 107 genes resulted in enrichment of a TGF-β superfamily signalling pathway (TGF-Core)
- and related gene ontology terms (Supplementary Table 15).

Functional enrichment analyses

- 312 Using stratified LD-score regression,⁴⁰ we showed that FEV₁/FVC and FVC heritability is significantly
- enriched at variants overlapping histone marks that are specific to lung, foetal lung, and smooth
- muscle-containing (i.e. colon and stomach) cell lines. SNPs that overlap with H3K4me1 marks that
- are specific to foetal lung cells correspond to 6.99% of the input SNPs yet explain 57.09% (P=2.85x10⁻¹
- 316 ²⁵) and 35.84% (P=4.19x10⁻²¹) of the SNP-chip heritability for FEV₁/FVC and FVC, respectively
- 317 (Supplementary Table 16).
- We also tested enrichment of (i) FEV₁/FVC and (ii) FVC SNPs at DNase I hypersensitive site (DHS)
- hotspots using GARFIELD⁴¹ (**Online Methods**). For FEV₁/FVC results, we see significant enrichment
- across most cell lines with increased fold-enrichment in foetal and adult lung, foetal muscle and
- 321 fibroblasts (Supplementary Figure 4A). For FVC, we see similar broad significant enrichment without
- evidence of increased enrichment in a subset of tissues (**Supplementary Figure 4B**). This suggests
- 323 that SNPs influencing FVC may act via more complex and broader developmental pathways.
- We used DeepSEA⁴² to identify whether our signals were predicted to have a chromatin effect in
- 325 lung-related cell lines. We identified 10 signals (including 5 new signals) for which the SNP with the
- 326 largest posterior probability of being causal also had a significant predicted effect on a DHS in lung-
- related cells (**Supplementary Table 17**). This included a new signal near *SMURF2* (17q24.1,
- 328 rs11653958).

329

Drug targets

- 330 All 107 putative causal genes were investigated for known gene-drug interactions⁴³ (**Supplementary**
- 331 Table 18). We highlight two examples of new genetic signals implicating targets for drugs in
- development for indications other than COPD. One of our new signals is an eQTL for ITGAV. ITGAV
- encodes a component of the $\alpha v\beta 6$ integrin heterodimer, which is inhibited by a monoclonal antibody
- in development for pulmonary fibrosis (NCT01371305) and for which the small molecule
- 335 GSK3008348 (NCT03069989) is an antagonist⁴⁴. Integrins have an emerging role as local activators of
- TGF β and specifically the avb6 integrin heterodimer can activate latent-TGF β ⁴⁵. In our study, the
- allele associated with reduced expression of ITGAV (Supplementary Table 13) was associated with
- increased lung function (**Supplementary Table 9**) suggesting that inhibitors of ανβ6 integrin might
- also have a beneficial effect in COPD. Another of our new signals is associated with expression of
- 340 TNFSF13 (synonym APRIL), a cytokine of the TNF ligand family. Atacicept blocks B cell stimulation by
- 341 TNFSF13 (as well as by BLyS) and reduced systemic lupus erythematosus disease activity in a recent

- Phase IIb trial⁴⁶. In our study, the allele associated with decreased expression of *TNFSF13* was
- associated with reduced FEV₁, indicating that vigilance for pulmonary consequences of atacicept
- 344 may be warranted.

345 Genetic Risk Score: association with FEV₁/FVC and COPD in multiple ancestries

- We constructed a genetic risk score (GRS) weighted by FEV₁/FVC effect sizes comprising all 279
- sentinel variants, and tested for association with FEV₁/FVC and GOLD Stage 2-4 COPD (FEV₁/FVC<0.7
- and FEV₁<80% predicted) in different ancestry groups in UK Biobank, and China Kadoorie Biobank
- 349 (Online Methods, Supplementary Table 19). UK Biobank participants of non-European ancestry
- 350 were not included in the discovery analyses. The GRS was associated with a significant decrease in
- 351 lung function, and corresponding significant increase in COPD risk in each of the independent
- ancestry groups (Figure 3a).
- We tested for a GRS interaction with smoking in European ancestry individuals in UK Biobank⁴⁷. No
- 354 statistical interaction was seen for FEV₁/FVC (interaction term -0.002 per SD change in GRS, 95% CI:
- 355 [0.009, 0.005], P=0.532), whilst the findings for COPD were consistent with a slightly smaller effect of
- the GRS in ever-smokers (OR for ever-smoking-GRS interaction term per SD change in GRS 0.96, 95%
- 357 CI: [0.92, 0.99], P=0.015).
- 358 The association of the GRS with COPD susceptibility was additionally tested in five independent
- 359 COPD case-control studies (**Supplementary Table 20, Online Methods**). Similar effect size estimates
- were seen across each of the 5 European ancestry studies (Figure 3b); in the meta-analysis of these
- 361 studies (n=6,979 cases and 3,915 controls), the odds ratio for COPD per standard deviation of the
- weighted GRS was 1.55 (95% CI: [1.48, 1.62]), P=2.87×10⁻⁷⁵ (**Supplementary Table 21**). The GRS was
- also associated with COPD in individuals of African-American ancestry in COPDGene (P=8.36×10⁻⁷),
- albeit with a smaller effect size estimate, odds ratio=1.26 (95% CI: [1.15, 1.37]).
- 365 To aid clinical interpretation, we divided individuals in each of the five European ancestry COPD
- 366 case-control studies into deciles, according to their value of the weighted GRS. The odds ratio for
- 367 COPD in members of the highest GRS decile compared to the lowest GRS decile was 4.73 (95% CI:
- 368 [3.79, 5.90]), P=3.00×10⁻⁴³ (Figure 3c, Supplementary Table 22). We calculated the population
- attributable risk fraction (Supplementary Note) and estimated that the proportion of COPD cases
- attributable to risk scores above the first GRS decile was 54.6% (95% CI: [50.6%, 58.4%]).
- 371 Incorporation of the GRS into a risk model already comprising available clinical information (age, sex,
- 372 height and pack-years of smoking in COPDGene non-Hispanic Whites) led to a statistically significant
- 373 (P=3.33×10⁻¹⁰), yet modest, increase in the area under the curve, from 0.751 to 0.771
- 374 (Supplementary Note). Based on our estimated GRS relative risk and absolute risk estimates of
- 375 COPD⁴⁸, one would expect the highest GRS risk decile group of smokers to have an absolute risk of
- developing COPD by approximately 70 years of age of 82.4%, versus 17.4% for the lowest GRS decile
- 377 (Supplementary Note).

Pleiotropy and phenome-wide association studies

- 379 As phenome-wide association studies (PheWAS) can provide evidence mimicking pharmacological
- interventions of drug targets in humans and informing drug development⁴⁹, we undertook a PheWAS
- of 2,411 phenotypes in UK Biobank (Online Methods, Figure 4, Supplementary Table 23); 226 of the
- 382 279 sentinel variants were associated (FDR<1%) with one or more traits and diseases (excluding
- 383 quantitative lung function traits). Eighty-five of the lung function signals were associated with

standing height. In order to investigate whether the genetic association signals for lung function were driven by incomplete adjustment for height, we tested for correlation of effects on lung function in UK Biobank and height in a meta-analysis of UK Biobank and the GIANT consortium for 246 of the 279 signals that had a proxy variant in GIANT⁵⁰; there was no significant correlation (**Supplementary Figure 5**). Additionally, the PheWAS revealed associations with body composition measures such as fat free mass (54 SNPs) and hip circumference (40 SNPs), as well as muscle strength (32 SNPs, grip strength). One hundred and fourteen of the 279 SNPs were associated with several quantitative measures of blood count, including eosinophil counts and percentages (25 SNPs). Twenty-five of our SNPs were also associated with asthma including 12 SNPs associated both with asthma and eosinophil measures (**Supplementary Table 24**). Eight of these SNPs were in LD (r²>0.1) with a SNP reported for association with asthma in previously published genome-wide association studies. We compared our observed effect sizes with those estimated after exclusion of all self-reported asthma cases and observed similar estimates (**Supplementary Figure 6**) suggesting that the lung function associations we report are not driven by asthma.

We examined the specificity of genetic associations, given the potential for this to predict specificity of drug target modification, and found that 53 of the 279 signals were associated only with lung function and COPD-related traits. In contrast, three of our 279 signals were associated with over 100 traits across multiple categories – among these rs3844313, a known intergenic signal near *HLA-DQB1* was associated with 163 traits, and also had the strongest signal in the PheWAS, which was for association with intestinal malabsorption and coeliac disease.

In our 279-variant weighted GRS PheWAS analysis (**Supplementary Table 25**), we found association with respiratory traits including COPD, chronic bronchitis, emphysema, respiratory failure, corticosteroid use and both paediatric and adult-onset asthma (**Figure 5a**). The GRS was also associated with non-respiratory traits including coeliac disease, an intestinal autoimmune disorder (**Figure 5b**). These pleiotropic effects on risk of autoimmune diseases was further confirmed by analysis of previously reported GWAS (**Online Methods, Supplementary Table 26**) which showed overlapping single variant associations with Crohn's disease, ulcerative colitis, psoriasis, systemic lupus erythematosus, IgA nephropathy, pediatric autoimmune disease and type 1 diabetes.

Discussion

The large sample size of our study, achieved by our refinement of the spirometry in UK Biobank and inclusion of the substantially expanded SpiroMeta consortium data set, has doubled the yield of lung function signals to 279. Fine-mapping of all new and previously reported signals, together with gene and protein expression analyses with improved tissue specificity and stringency, has implicated new genes and pathways, highlighting the importance of cilia development, TGF- β signalling via SMAD3, and elastic fibres in the aetiology of airflow obstruction. Many of the genes and pathways reported here contain druggable targets; we highlight examples where the genetic variants mimicking therapeutic modulation of targets may have opposing effects on lung function. We have developed and applied the first weighted GRS for lung function and tested it in independent COPD case-control studies. Our GRS shows stronger association and larger effect size estimates than a previous GRS in European ancestry populations¹⁸, as well as generalisability to other ancestry groups. We undertook the first comprehensive PheWAS for lung function signals, and report genetic variants with apparent specificity of effects and others with pleiotropic effects that might indicate shared biological pathways between different diseases.

428 For the first time in a GWAS of lung function, we report an enrichment of genes involved in 429 ciliogenesis (including KIAA0753, CDK2 and CEP72). Defects in primary cilia as a result of highly 430 deleterious mutations in essential genes result in ciliopathies known to affect multiple organ 431 systems. We found an enrichment of genes with a role in centriolar replication and duplication, core 432 processes in primary and motile cilia formation. Mutations in KIAA0753 cause the ciliopathies Joubert Syndrome and Orofaciodigital Syndrome²⁸. Reduced airway motile cilia function impacting 433 434 mucus clearance is a feature of COPD, but it has not been clear whether this is causal or the 435 consequence of damage by external factors such as smoking or infection. Our findings suggest that 436 impaired ciliary function might be a driver of the disease process. We have previously shown 437 enrichment of rare variants in cilia-related genes in heavy smokers without airflow obstruction⁵¹. 438 New signals, implicating ITGAV and GDF5, as well as stronger support for TGFB2 and MFAP2 as likely 439 causal genes, provide new genetic support for the importance of elastic fibre pathways in lung 440 function and COPD¹⁸. The elastic fibres of the extracellular matrix are known to be disrupted in 441 COPD⁵². As the breakdown of elastic fibres by neutrophil elastase leads to emphysema in individuals 442 with alpha₁-antitrypsin deficiency, we also assessed the association with the SERPINA1 Z allele, 443 which was not associated with FEV₁/FVC in our study (rs28929474, P=0.109 in UK Biobank). 444 Smoking and genetic risk both have important effects on lung function and COPD. For lung function, 445 we found no interaction between smoking and individual variants, and for FEV₁/FVC no interaction 446 between smoking status and the weighted GRS. However, for COPD a weak smoking-GRS interaction 447 was observed. Whilst the weighted GRS showed a strong association with COPD susceptibility, and a 448 high attributable risk, we do not claim that this would represent an appropriate method of screening 449 for COPD risk. Importantly, our findings demonstrate the high absolute risk among genetically 450 susceptible smokers (82.4% by approximately 70 years of age). 451 The unprecedented sample size of UK Biobank as a single cohort has revolutionised genetic studies. 452 We used two complementary study designs to maximise sample size for discovery and ensure 453 robustness of findings by requiring independent support for association. Furthermore, through 454 additional analysis of the spirometry data in UK Biobank and substantial expansion of the SpiroMeta 455 consortium, we have markedly increased samples sizes to almost seven times those included in 456 previous studies. As no lower MAF threshold was applied in our analyses, an overall threshold of 457 P<5×10⁻⁹, as recommended for re-sequencing analyses of European ancestry individuals²³, was applied. We identified the largest number of new signals in our more stringent two-stage design 458 459 ("Tier 1", 99 new signals). Amongst the signals that we report as "Tier 3" (and did not include in 460 further analyses), all reached P<10⁻³ in UK Biobank and 183 met a less stringent threshold of P<0.05 in SpiroMeta. As the primary objective of our paper was to identify variants that were robustly 461 462 associated with lung function and COPD; we did not include the Tier 3 signals in the downstream 463 analyses. However, as a GRS based on fuller sets of variants are likely to add power for genetic 464 prediction, we have made available our Tier 3 signals (and genome-wide findings) to the scientific 465 community. 466 Our study is the first to investigate genome-wide associations with PEF. PEF is determined by various 467 physiological factors including lung volume, large airway calibre, elasticity of the lung and expiratory muscle strength, is used for monitoring asthma, and was incorporated in a recently evaluated clinical 468 469 score for diagnosing COPD and predicting acute exacerbations of COPD⁵³. Overall, 133 of the 279

signals were also associated with PEF (P<10⁻⁵) and for 15 signals (including 4 new signals), PEF was

- 471 the most significantly associated trait. Of note, a signal near SLC26A9, a known cystic fibrosis
- 472 modifier gene⁵⁴, was highly significantly associated with PEF in UK Biobank (P=3.97×10⁻⁶⁶) and
- 473 nominally significant in SpiroMeta (P=6.93×10⁻³), with consistent direction of effect, but did not meet
- 474 the Tier 2 criteria. This could reflect the limited power for PEF in SpiroMeta (up to 24,218 for PEF
- 475 compared to 79,055 for the other traits).
- 476 Examining associations of a given genetic variant with a wide range of human phenotypes is a
- 477 valuable tool in therapeutic target validation. As in our PheWAS, it can highlight variants which show
- 478 associations with one or more respiratory traits that might be expected to demonstrate greater
- 479 target specificity than variants associated with many traits. Additionally, in some instances,
- 480 association with multiple traits may indicate the relevance of drug repurposing. Association of a
- 481 given SNP with multiple traits does not necessarily imply shared aetiology, and further investigation
- is warranted. Our GRS PheWAS assesses broader genetic overlap between lung function and other
- traits and supports the evidence for some shared genetic determinants with autoimmune diseases.
- Our study did not assess interaction of the signals with factors other than smoking, further studies
- 485 might include assessments for interaction effects, for example, with sex, air pollution and dietary
- 486 intake. We did not analyse variants on the sex chromosomes as those data were not available at the
- 487 time of our study.
- In summary, our study has doubled the number of signals for lung function and provides new
- 489 understanding and resources of utility for the development of therapeutics. The 279-variant GRS we
- 490 constructed was associated with a 4.73-fold increased relative risk of moderate-severe COPD
- 491 between highest and lowest deciles, such that one would expect over 80% of smokers in the highest
- 492 genetic risk decile to develop COPD. The GRS was also predictive of COPD across multiple ancestral
- 493 groups. Our PheWAS highlights both expected and unexpected associations relevant to respiratory
- and other systemic diseases. Investigating the nature of the pleiotropic effects of some of these
- 495 variants will be of benefit for drug target identification and validation.

Online Methods

496 497

Study Design Overview and rationale

- 498 For the two-stage approach, we firstly selected distinct signals of association (defined using
- 499 conditional analyses) with one or more traits achieving P<5×10⁻⁹ in UK Biobank only (n up to
- 321,047). A threshold of P<5×10⁻⁹ was selected to maximise stringency of findings and to be
- 501 consistent with currently recommended genome-wide significance thresholds for re-sequencing
- analyses of European ancestry individuals²³. We then reported as new those signals which
- additionally met P<10⁻³ in SpiroMeta (N effective>70% of n up to 79,055; see **Supplementary Note**
- and Supplementary Figure 7 for power calculations), with consistent directions of effect and term
- them "Tier 1" signals as they meet our highest level of stringency. Methods for conditional analyses
- and determining novelty are described below.
- For the one-stage approach, we selected distinct signals of association (defined using conditional
- analyses) with one or more traits reaching P<5×10⁻⁹ in the meta-analysis of UK Biobank and
- 509 SpiroMeta (n up to 400,102) and reported as new those which additionally met P<10⁻³ in both UK
- Biobank and SpiroMeta with a consistent direction of effect. We term these signals "Tier 2" as they
- 511 meet our second-highest level of stringency.

- All signals meeting either set of criteria described above, and that had not been previously
- 513 published, were reported as new signals of association with lung function. Signals that reached
- P<5×10⁻⁹ in the meta-analysis of UK Biobank and SpiroMeta, had a consistent direction of effect in
- 515 UK Biobank and SpiroMeta, but which did not reach P<10⁻³ in both UK Biobank and SpiroMeta are
- presented as "Tier 3" and were not included in further analyses.
- Data for chromosome X were available for 321,027 European individuals in UK Biobank and 38,199
- 518 individuals from SpiroMeta (1000 Genomes Project Phase 1 imputation).⁵⁵

519 UK Biobank

- The UK Biobank data resource is described elsewhere (http://www.ukbiobank.ac.uk). Individuals
- were selected for inclusion in this study if they met the following criteria: (i) had complete data for
- age, sex, height and smoking status; (ii) had spirometry meeting quality control requirements (based
- on analyses of acceptability, reproducibility and blow curve metrics; Supplementary Note); (iii) had
- 524 genome-wide imputed genetic data and; (iv) were of European ancestry based on genetic data
- (Supplementary Note; Supplementary Figure 1). Genotyping was undertaken using the Affymetrix
- 526 Axiom® UK BiLEVE and UK Biobank arrays¹³. Genotypes were imputed to the Haplotype Reference
- 527 Consortium panel⁵⁶ (**Supplementary Note**), and retained if minor allele count≥3 and imputation
- quality (info)>0.5. A total of 321,047 individuals were included in this analysis (**Supplementary Table**
- 529 **1**).

541

- Residuals from linear regression of each trait (FEV₁, FVC, FEV₁/FVC and PEF) against age, age², sex,
- height, smoking status (ever/never) and genotyping array were ranked and inverse-normal
- transformed to obtain adjusted, normally distributed Z-scores. These Z-scores were then used for
- 533 genome-wide association testing under an additive genetic model using BOLT-LMM v2.3²⁰. Principal
- 534 components were not included as BOLT-LMM uses a linear mixed model to account for relatedness
- 535 and fine-scale population structure.
- 536 Linkage disequilibrium (LD) score regression implemented in LDSC²¹ was used to estimate inflation of
- test statistics due to confounding. Genomic control was applied, adjusting all test statistics by LD
- 538 score regression intercepts: 1.12 for FEV₁, 1.14 for FVC, 1.19 for FEV₁/FVC and 1.13 for PEF
- 539 (Supplementary Figure 8; Supplementary Table 27), acknowledging that this might be over-
- 540 conservative for UK Biobank.

SpiroMeta consortium

- The SpiroMeta consortium meta-analysis was comprised of a total of 79,055 individuals from 22
- 543 studies. Thirteen studies (n=21,436 individuals) were imputed to the 1000 Genomes Project Phase 1
- reference panel⁵⁵ (B58C, BHS1&2, three Croatian studies [CROATIA-Korcula, CROATIA-Split and
- 545 CROATIA-Vis], Health 2000, KORA F4, KORA S3, LBC1936, NSPHS, ORCADES, SAPALDIA and YFS) and 9
- 546 studies (n=61,682 individuals) were imputed to the Haplotype Reference Consortium (HRC) panel⁵⁷
- 547 (EPIC [obese cases and population-based studies], GS:SFHS, NFBC1966, NFBC1986, PIVUS, SHIP,
- 548 SHIP-TREND, UKHLS and VIKING). See **Supplementary Tables 2** and **3** for the definitions of all
- abbreviations, study characteristics, details of genotyping platforms and imputation panels and
- methods). Measurements of spirometry for each study are described in the **Supplementary Note**.
- In each study, linear regression models were fitted for each lung function trait (FEV₁, FEV₁/FVC, FVC
- and PEF, where available), with adjustment for age, age², sex and height. For studies with unrelated
- 553 individuals, these models were fitted separately in ever smokers and never smokers, with additional

- adjustment for principal components of ancestry. Studies with related individuals fitted mixed
- models in all individuals to account for relatedness, with ever smoking status as a covariate.
- In all studies, rank-based inverse normal transformations were undertaken on the residuals, with
- these transformed residuals used as the phenotype for association testing under an additive genetic
- 558 model (Supplementary Table 3).
- In the study level results, variants were excluded if they had a very low minor allele count (MAC)
- 560 (Supplementary Table 3) or imputation quality (info)<0.3. In studies with unrelated individuals, the
- 561 ever and never smokers results were combined, using inverse variance weighted meta-analysis, to
- 562 give an overall study result. Genomic control was then applied to all study level results, before
- 563 combining results across all studies using inverse variance weighted meta-analysis. LD score
- regression intercepts for the meta-analysis were close to 1.00 (Supplementary Figure 8;
- 565 **Supplementary Table 27**) and so genomic control was not applied.
- 566 Meta-analyses

570

583

- A total of 19,871,028 variants (imputed or genotyped) in both UK Biobank and SpiroMeta were
- 568 meta-analysed using inverse-variance weighted fixed effect meta-analysis, and no further genomic
- control was applied as LD score regression intercepts were close to 1.00 (Supplementary Table 27).
 - Selection of new signals using conditional analyses
- All SNPs ±1Mb were extracted around each sentinel variant. GCTA⁵⁸ was then used to perform
- 572 stepwise conditional analysis to select independently associated SNPs within each 2Mb region. LD
- 573 was estimated for UK Biobank from the same individuals used in discovery, and for SpiroMeta, from
- an unrelated subset of 48,943 UK Biobank individuals¹⁸. Any secondary signals identified within each
- 2Mb region were required to meet Tier 1 or Tier 2 criteria (described above) after conditioning on
- the primary sentinel variant. A combined list of distinct lung function signals was then made across
- the 4 phenotypes, FEV₁, FVC, FEV₁/FVC and PEF as follows: where sentinel variants for 2 signals for
- 578 different phenotypes were in high LD (r²>0.5), we retained the most significant variant; where 2
- signals were in moderate LD (0.1>r²>0.5), we retained variants if, after conditional analysis, they still
- met the Tier 1 or Tier 2 threshold; for signals in low LD ($r^2 < 0.1$) we retained both variants. We then
- used the same criteria to identify a subset of new signals which were distinct from previously
- 582 published independent signals (see below).

Assessment of previously reported lung function signals

- We identified 184 autosomal signals from previous GWAS analyses of lung function and COPD^{1,4-14}.
- After LD pruning (keeping only those signals with LD of r²<0.1), we removed 24 non-independent
- 586 SNPs, leaving 160 previously reported independent signals. Of 6 previously reported signals in the
- 587 HLA region, we included only the 3 independent lung function HLA signals reported from conditional
- analysis using all imputed HLA genotypes¹⁸: AGER (rs2070600), HLA-DQB1 (rs114544105) and near
- 589 ZNF184 (rs34864796) leaving 157 signals.
- We confirmed association of previously reported signals in our data if they met any of three criteria:
- 591 (i) the previously reported sentinel was associated (P<10⁻⁵) with any lung function trait in UK
- Biobank; (ii) a proxy for the previously reported sentinel with r²>0.5 was associated (P<10⁻⁵) with any
- 593 lung function trait in UK Biobank; (iii) a proxy for the previously reported sentinel with r²>0.1 was
- associated with any lung function trait meeting tier 1 or tier 2 criteria (Supplementary Figure 3).

Effect on COPD susceptibility – genetic risk score in multiple ancestries

- To test association of all lung function signals and COPD susceptibility, we constructed a 279-variant weighted GRS comprising the 139 novel and 140 previously reported signals; we used the previously reported sentinel SNP for published signals. Weights were derived using the FEV₁/FVC ratio decreasing (COPD risk *increasing*) alleles. For previously reported signals (n=140), results from the UK Biobank analysis were used to derive weights for the 94 signals that were not discovered using UK Biobank data and weights were taken from SpiroMeta for 46 signals where UK Biobank was
- 602 included in the discovery of those signals. For novel signals identified in this study, weights were
- taken from SpiroMeta for two-stage (tier 1) signals (n=99), and the smallest absolute effect size from
- either of UK Biobank or SpiroMeta was used for one-stage (tier 2) signals (n=40) (Supplementary
- Table 28). This approach was taken in order to derive conservative weights for each variant, thus
- reducing the likelihood of bias by winner's curse. For the weighted GRS the number of risk alleles at
- each variant was multiplied by its weight.
- The GRS was first calculated in unrelated individuals (KING kinship coefficient of<0.0884) within 6
- ancestral groups of UK Biobank: Europeans, South Asians, Africans, Chinese, Mixed African and
- 610 Europeans, and Mixed Other (total sample of unrelated individuals across six ancestries: 323,001)
- using PLINK. Weights and alleles were as described above. COPD was defined as FEV₁/FVC<0.7 and
- 612 FEV₁<0.8 of the predicted value, i.e. GOLD stage 2-4 categorisation. Associations with the GRS were
- then tested using COPD (in ancestral groups with at least 100 COPD cases) and FEV₁/FVC as the
- 614 outcomes.

- 615 In addition, we calculated the GRS in individuals from the China Kadoorie Biobank (CKB). Four of the
- 616 279 SNPs were not available in CKB (rs1800888, rs56196860, rs72724130 and rs77672322), and for
- 617 12 SNPs, proxies were used (minimum r²=0.3). Analyses were undertaken in all COPD GOLD stage 2-4
- cases (FEV₁/FVC<0.7 and FEV₁<0.8 of the predicted value, in 6,013 cases and 69,567 controls),
- against an unbiased set of population controls. The GRS was also tested for association with
- 620 FEV₁/FVC in CKB (n=72,796).
- 621 Logistic regression of COPD case-control status with the GRS in UK Biobank and China Kadoorie
- 622 Biobank assumed an additive genetic effect and was adjusted for age, age², sex, height, and smoking
- 623 (Supplementary Table 19). Ten principal components were also included in UK Biobank analyses. In
- 624 China Kadoorie Biobank, analyses were stratified by geographical regions and then meta-analysed
- using an inverse-variance fixed effect model. Linear models assessing the association with FEV₁/FVC
- were fitted using the same transformed outcome as in the main GWAS analysis.
- We then tested association in 5 European ancestry COPD case-control studies: COPDGene (Non-
- 628 Hispanic White Population) (3,068 cases and 2,110 controls), ECLIPSE (1,713 cases and 147 controls),
- 629 GenKOLS (836 cases and 692 controls), NETT-NAS (374 cases and 429 controls) and SPIROMICS (988
- cases and 537 controls) (Supplementary Table 20). In addition, we tested this GRS in the COPDGene
- 631 African American population study (910 cases and 1,556 controls). Logistic regression models using
- 632 COPD as outcome and the GRS as exposure were adjusted for age, age², sex, height, and principal
- components (Supplementary Table 21, Supplementary Figure 9). Single variant associations of the
- 279 SNPs with COPD are in **Supplementary Table 29.**
- 635 Next, we divided individuals in the external COPD case-control studies into deciles according to their
- values of the weighted GRS. This was undertaken separately by study group, and for each decile

- 637 logistic models were fitted, comparing the risk of COPD for members of each decile group compared
- to those in the lowest decile (i.e. those with lowest values of the weighted GRS). Covariates were as
- 639 for the COPD analyses. Results were combined across European-ancestry study groups by fixed
- effect meta-analysis (Supplementary Table 22).

Effects on smoking behaviour

- As our discovery GWAS in UK Biobank was adjusted for ever vs. never smoking status, and not for
- pack years of smoking (pack years information was missing for 32% of smokers), we evaluated
- whether any signals of association with lung function might be driven by an association with smoking
- behaviour by testing for association with smoking initiation (123,890 ever smokers vs. 151,706 never
- smokers) and cigarettes per day (n=80,015) in UK Biobank (full methods in **Supplementary Note**).
- We also tested for association with lung function in never smokers only (n=173,658). We excluded
- any signals associated with smoking behaviour (Supplementary Table 6), but not with lung function
- in never smokers.

641

650

665

Smoking interaction

- 651 For associated variants (new and previously reported), we repeated association testing for lung
- 652 function separately in UK Biobank and SpiroMeta (up to 176,701 ever smokers and 197,999 never
- smokers), and tested for an interaction effect with smoking using the Welch test (Supplementary
- Note). A threshold of P<1.79×10⁻⁴ (Bonferroni corrected for 279 tests) indicated significance.
- We further tested for interaction between the weighted GRS and smoking, within 303,619 unrelated
- 656 individuals of European ancestry in UK Biobank, using COPD and FEV₁/FVC as outcomes (the
- 657 FEV₁/FVC phenotype was pre-adjusted for age, age² sex, and height, and the residuals transformed
- as per the main GWAS analysis). For COPD (defined as FEV₁/FVC<0.7, and FEV₁<80% predicted) the
- 659 following logistic model was fitted:
- 660 COPD \sim genotyping array + 10 principal components + age + age² + sex + height + smoking status +
- weighted risk score + (smoking status × weighted risk score).
- For FEV₁/FVC the following linear model was fitted:
- 663 FEV₁/FVC ~ genotyping array + 10 principal components + smoking status + weighted risk score +
- 664 (smoking status x weighted risk score).

Proportion of variance explained

- We calculated the proportion of variance explained by each of the previously reported (n=140) and
- new variants (n=139) associated with lung function using the formula:

668
$$\frac{\sum_{i=1}^{n} 2f_i (1 - f_i) \beta_i^2}{V}$$

- where n is the number of variants f_i and θ_i are the frequency and effect estimate of the i'th variant,
- and V is the phenotypic variance (always 1 as our phenotypes were inverse-normal transformed).
- We used the same conservative effect estimates (β) as used to calculate GRS weights at the same set
- of 279 sentinel variants used for the GRS, which uses either UK Biobank or SpiroMeta effect
- 673 estimates (described above). Our previously published estimate of proportion of variance
- explained¹⁸ used effect estimates derived from UK Biobank. We assumed a heritability of 40%^{24,25} to
- estimate the proportion of additive polygenic variance.

676 Fine-mapping

685

- A Bayesian method⁵⁹ was used to fine-map lung-function-associated signals to the set of variants
- that were 99% likely to contain the underlying causal variant (assuming that the causal variant has
- been analysed). This was undertaken for new signals and for previously reported signals reaching
- 680 P<10⁻⁵ in UK Biobank. For the previously reported signals, the top sentinel variant from the current
- analysis in UK Biobank was used, instead of the previously reported variant. We used a value of 0.04
- for the prior W in the approximate Bayes factor formula⁶⁰. Effect sizes and standard errors for fine-
- 683 mapping were obtained from an inverse variance weighted meta-analysis of UK Biobank and
- SpiroMeta (n up to 400,102). Signals in the HLA region were not included.

Implication of potentially causal genes

- 686 Annotation of deleterious variants
- Variants in the 99% credible sets were checked for predicted functional effect if they were
- annotated as "exonic", "splicing", "ncRNA_exonic", "5'-UTR" or "3'-UTR" (untranslated region) by
- 689 ANNOVAR⁶¹. We then used SIFT, PolyPhen-2 (implemented using the Ensembl GRCh37 Variant
- 690 Effect Predictor, https://www.ensembl.org/vep, accessed 1 February 2018) and FATHMM⁶² to
- annotate missense variants, and CADD (also implemented using VEP) to annotate non-coding
- variation. Variants were annotated as deleterious in our study if they were labelled 'deleterious' by
- 693 SIFT, 'probably damaging' or 'possibly damaging' by PolyPhen-2, 'damaging' by FATHMM (specifying
- the 'Inherited disease' option of the coding variants methods, and setting the prediction algorithm
- to 'Unweighted') or had a CADD scaled score ≥20⁴. The union of the four methods was taken to
- 696 establish the number of potentially deleterious variants and their unique genes.
- 697 Gene expression and protein levels
- 698 At 276 of 279 (3 HLA signals excluded) signals, the sentinel variant and 99% credible set⁵⁹ were used
- to query three eQTL resources: lung eQTL (n=1,111)¹³, blood eQTL (n=4,896)⁶³ and GTEx (V7; with n
- up to 388 depending on tissue: Artery Aorta (n=267), Artery Coronary (n=152), Artery Tibial (n=388),
- 701 Colon Sigmoid (n=203), Colon Transverse (n=246), Esophagus Gastroesophageal Junction (n=213),
- 702 Esophagus Muscularis (n=335), Lung (n=383), Small Intestine Terminal Ileum (n=122), Stomach
- 703 (n=237), and Whole Blood (n=369)) 64 , and one blood pQTL resource (n=3,301) 39 .
- A gene was classified as a 'putative causal gene' if the sentinel SNP or any SNP in the respective 99%
- 705 credible set was associated with expression of this gene or its protein levels (FDR<5% for eQTL,
- P<5.03×10⁻⁸ [for 276 tests at 3,600 proteins] for pQTL) and if the GWAS sentinel SNP or any SNP in
- 707 the respective 99% credible set was also the variant most strongly associated with expression of the
- respective gene or level of the respective protein (i.e. the sentinel eQTL/pQTL SNP) in one or more of
- 709 the eQTL and pQTL data sets.

Pathway analysis

- 711 We tested for enrichment of genes identified via variant function annotation, gene expression or
- protein level analyses in pathway and gene set ontology databases using ConsensusPathDB.⁶⁵
- 713 Pathways or gene sets represented entirely by genes implicated by the same association signal were
- 714 excluded. Gene sets and pathways with FDR<5% are reported.

Functional enrichment analyses

- 716 We carried out stratified LD score regression to identify significant enrichment of heritability at
- variants overlapping histone marks (e.g. H3K4me1, H3K4me3) that are specific to lung, foetal lung,
- 718 and smooth muscle containing (i.e. colon, stomach) cell lines using methods specified by Finucane et
- 719 al.⁴⁰

715

- 720 We separately selected FEV₁/FVC and FVC associated SNPs passing two thresholds (P<5×10⁻⁵ and
- 721 P<5×10⁻⁹ in the meta-analysis) as input to GARFIELD⁴¹ to test for enrichment of our signals for 424
- 722 DHS hotspot annotations derived from 55 different tissues in the RoadMap Epigenomics project and
- 723 the ENCODE projects.
- Using DeepSEA⁴², we analysed all SNPs in the 99% credible set for predicted chromatin effects. We
- reported effects for any chromatin effect and lung-related cell line that had an E-value<0.05 (i.e. the
- 726 expected proportion of SNPs with a larger predicted effect based on empirical distributions of
- 727 predicted effects for 1000 Genomes SNPs) and an absolute difference in probability of>0.1
- 728 (threshold for "high confidence") between the reference and alternative allele.

Drug targets

729

- 730 Genes identified as potentially causal using eQTL, pQTL or variant annotation were interrogated
- 731 against the gene-drug interactions table of the Drug-Gene Interactions Database (DGIDB)
- 732 (http://www.dgidb.org/data/), accessed 16th October 2017. Drugs were mapped to CHEMBL IDs
- 733 (https://www.ebi.ac.uk/chembl/drug/indications), and indications (as MeSH headings) were added.

734 Phenome-wide association studies

- 735 To identify whether the 279 signals overlap with signals of association for other traits and diseases,
- 736 the weighted GRS was calculated in up to 379,337 UK Biobank samples, and a phenome-wide
- association study (PheWAS) was performed, with the GRS as the exposure. Traits included UK
- 738 Biobank baseline measures (from questionnaires and physical measures), self-reported medication
- vsage, and operative procedures, as well as those captured in Office of Population Censuses and
- 740 Surveys codes from the electronic health record. We also included self-reported disease variables
- and those from hospital episode statistics (ICD-10 codes truncated to three-character codes and
- combined in block and chapter groups), combining these where possible to maximise power. The
- 743 GRS analysis included 2,453 traits, and the single-variant analysis contained 2,411 traits (traits
- vith>200 cases were included for the single-variant PheWAS, whereas traits with>50 cases were
- included in the GRS PheWAS). Analyses were conducted in unrelated European-ancestry individuals
- 746 (KING kinship coefficient <0.0442), and were adjusted for age, sex, genotyping array, and ten
- 747 principal components. Logistic and linear models were fitted for binary and quantitative outcomes,
- 748 respectively. False discovery rates were calculated on the basis of the number of traits in the GRS
- and single-variant PheWAS (2,453 or 2,411, respectively).
- 750 In addition, the sentinel variants and variants within the 99% credible sets were queried against the
- 751 GWAS catalog⁶⁶ (https://www.ebi.ac.uk/gwas/, accessed 5th February 2018) and GRASP⁶⁷
- 752 (https://grasp.nhlbi.nih.gov/Overview.aspx, accessed 6th February 2018) for associations reported
- 753 at P<5×10⁻⁸. Associations relating to methylation, expression, metabolite or protein levels, as well as
- 754 lung function and COPD, were not included.

756 Acknowledgments

- 757 This research used the ALICE and SPECTRE High Performance Computing Facilities at the University
- 758 of Leicester. This research has been conducted using the UK Biobank Resource under application
- 759 648

- Donald P Tashkin, MD; Mary Beth Scholand, MD; J Michael Wells, MD; Robert A Wise, MD; and
- Prescott G Woodruff, MD, MPH. The project officers from the Lung Division of the National Heart,
- 829 Lung, and Blood Institute were Lisa Postow, PhD, and Thomas Croxton, PhD, MD.
- 830 DeepSEA: The DeepSEA project was primarily supported by US National Institutes of Health (NIH)
- grants R01 GM071966 to O.G.T and supported in part by US NIH grant P50 GM071508. O.G.T. is a
- 832 senior fellow of the Genetic Networks program of the Canadian Institute for Advanced Research
- 833 (CIFAR): Jian Zhou and Olga G Troyanskaya carried out SNV effect prediction analyses in an updated
- version of DeepSEA (deepsea.princeton.edu), which contained more lung-related cell lines than the
- original version published in Nature Methods in August 2015
- 836 (www.nature.com/articles/nmeth.3547).
- 837 GSK: This research has been conducted using the UK Biobank Resource under application number
- 838 26041.

- 839 B58C: Genotyping for the B58C-WTCCC subset was funded by the Wellcome Trust (076113/B/04/Z).
- 840 The B58C-T1DGC genotyping utilized resources provided by the Type 1 Diabetes Genetics
- 841 Consortium, a collaborative clinical study sponsored by the National Institute of Diabetes and
- Digestive and Kidney Diseases (NIDDK), National Institute of Allergy and Infectious Diseases (NIAID),
- National Human Genome Research Institute (NHGRI), National Institute of Child Health and Human
- 844 Development (NICHD), and Juvenile Diabetes Research Foundation International (JDRF) and
- 845 supported by U01 DK062418. B58C-T1DGC GWAS data were deposited by the Diabetes and
- 846 Inflammation Laboratory, Cambridge Institute for Medical Research (CIMR), University of
- 847 Cambridge, which is funded by Juvenile Diabetes Research Foundation International, the Wellcome
- 848 Trust and the National Institute for Health Research Cambridge Biomedical Research Centre; the
- 849 CIMR is in receipt of a Wellcome Trust Strategic Award (079895). The B58C-GABRIEL genotyping was
- 850 supported by a contract from the European Commission Framework Programme 6 (018996) and
- grants from the French Ministry of Research.
- 852 BHS: Generous support for the 1994/5 follow-up study from Healthway, Western Australia, and
- 853 support from The Great Wine Estates of the Margaret River region of Western Australia. The study
- also acknowledges the numerous Busselton community volunteers who assisted with data collection
- and the study participants from the Shire of Busselton.
- 856 CROATIA-Korcula/Split/Vis: MRC, the Ministry of Science, Education and Sport in the Republic of
- 857 Croatia (216-1080315-0302) and the Croatian Science Foundation (grant 8875) (funding to I. Rudan,
- 858 C. Hayward, S.M. Kerr, O. Polasek, V. Vitart, and J. Marten).
- H2000: Medical Research Fund of the Tampere University Hospital.
- 860 KORA F4 and KORA S3: The KORA study was initiated and financed by the Helmholtz Zentrum
- München German Research Center for Environmental Health, which is funded by the German
- 862 Federal Ministry of Education and Research (BMBF) and by the State of Bavaria. Furthermore, KORA
- 863 research was supported within the Munich Center of Health Sciences (MC-Health), Ludwig-
- Maximilians-Universität, as part of LMUinnovativ and by the Competence Network Asthma and
- 865 COPD (ASCONET), network COSYCONET (subproject 2, BMBF FKZ 01GI0882) funded by the German
- 866 Federal Ministry of Education and Research (BMBF)
- LBC1936: Phenotype collection in the Lothian Birth Cohort 1936 was supported by Age UK (The
- 868 Disconnected Mind project). Genotyping was funded by the Biotechnology and Biological Sciences
- 869 Research Council (BBSRC). The work was undertaken by The University of Edinburgh Centre for
- 870 Cognitive Ageing and Cognitive Epidemiology, part of the cross council Lifelong Health and Wellbeing
- 871 Initiative (MR/K026992/1). Funding from the BBSRC and MRC is gratefully acknowledged.
- 872 NSPHS: Swedish Medical Research Council (K2007-66X-20270-01-3, 2011-5252, 2012-2884 and
- 873 2011-2354), the Foundation for Strategic Research (SSF). NSPHS as part of European Special
- Populations Research Network (EUROSPAN) was also supported by the European Commission FP6
- 875 STRP (01947, LSHG-CT-2006-01947).
- ORCADES: Supported by the Chief Scientist Office of the Scottish Government (CZB/4/276,
- 877 CZB/4/710), the Royal Society, the MRC Human Genetics Unit, Arthritis Research UK and the
- 878 European Union framework program 6 EUROSPAN project (contract no. LSHG-CT-2006-018947).
- 879 ORCADES DNA extractions were performed at the Wellcome Trust Clinical Research Facility in
- 880 Edinburgh.

- SAPALDIA: Swiss National Science Foundation (33CS30-148470/1&2, 33CSCO-134276/1, 33CSCO-

- 900 Responsibility area of Kuopio, Tampere and Turku University Hospitals (grant X51001); Juho Vainio
- 901 Foundation; Paavo Nurmi Foundation; Finnish Foundation for Cardiovascular Research; Finnish
- 902 Cultural Foundation; Tampere Tuberculosis Foundation; Emil Aaltonen Foundation; Yrjö Jahnsson
- 903 Foundation; Signe and Ane Gyllenberg Foundation; Diabetes Research Foundation of Finnish
- 904 Diabetes Association; and EU Horizon 2020 (grant 755320 for TAXINOMISIS)
- 905 EPIC: Cancer Research UK and the MRC. The authors thank the participants, General Practitioners
- and staff of the EPIC-Norfolk study team, and collaborators for their contribution.
- 907 Generation Scotland: Chief Scientist Office of the Scottish Government Health Directorate
- 908 (CZD/16/6), the Scottish Funding Council (HR03006), Medical Research Council UK, and a Wellcome
- 909 Trust Strategic Award 'STratifying Resilience and Depression Longitudinally'
- 910 (104036/Z/14/Z)(STRADL). Genotyping of the GS:SFHS samples was carried out by the Edinburgh
- 911 Clinical Research Facility, University of Edinburgh. We are grateful to all the families who took part in
- 912 the Generation Scotland: Scottish Family Health Study, the general practitioners and Scottish School
- of Primary Care for their help in recruiting them, and the whole Generation Scotland team, which
- 914 includes academic researchers, IT staff, laboratory technicians, statisticians and research managers.
- 915 NFBC1966 and NFBC1986: NFBC1966 and 1986 have received financial support from the Academy of
- 916 Finland (project grants 104781, 120315, 129269, 1114194, 24300796, Center of Excellence in
- 917 Complex Disease Genetics and SALVE), University Hospital Oulu, Biocenter, University of Oulu,
- 918 Finland (75617), NIHM (MH063706, Smalley and Jarvelin), Juselius Foundation, NHLBI grant
- 919 5R01HL087679-02 through the STAMPEED program (1RL1MH083268-01), NIH/NIMH
- 920 (5R01MH63706:02), the European Commission (EURO-BLCS, Framework 5 award QLG1-CT-2000-
- 921 01643), ENGAGE project and grant agreement HEALTH-F4-2007-201413, EU FP7 EurHEALTHAgeing -
- 922 277849, the Medical Research Council, UK (G0500539, G0600705, G1002319, PrevMetSyn/SALVE)
- and the MRC, Centenary Early Career Award. The program is currently being funded by the H2020

- 924 DynaHEALTH action (grant agreement 633595), EU H2020-HCO-2004 iHEALTH Action (grant
- 925 agreement 643774), EU H2020-PHC-2014 ALEC Action (grant agreement No. 633212), EU H2020-
- 926 SC1-2016-2017 LifeCycle Action (grant agreement No 733206), EU H2020-MSCA-ITN-2016 CAPICE
- 927 Action (grant agreement 721567), Academy of Finland EGEA-project (285547) and MRC Grant nro
- 928 MR/M013138/1.
- 929 PIVUS: Swedish Research Council, Swedish Heart-Lung Foundation, Swedish Diabetes Foundation
- 930 and Uppsala University. Genotyping and analysis was funded by the Wellcome Trust under awards
- 931 WT064890 and WT098017. The PIVUS investigators express their deepest gratitude to the study
- 932 participants.
- 933 SHIP / SHIP-Trend: Federal Ministry of Education and Research (01ZZ9603, 01ZZ0103, 01ZZ0403,
- 934 03ZIK012), and the German Research Foundation (GR 1912/5-1).
- 935 UKHLS: Economic and Social Research Council (ES/H029745/1). These data are from Understanding
- 936 Society: The UK Household Longitudinal Study, which is led by the Institute for Social and Economic
- 937 Research at the University of Essex and funded by the Economic and Social Research Council. The
- 938 data were collected by NatCen and the genome wide scan data were analysed by the Wellcome
- 939 Trust Sanger Institute. The Understanding Society DAC have an application system for genetics data
- and all use of the data should be approved by them. The application form is at:
- 941 https://www.understandingsociety.ac.uk/about/health/data. A full list of authors is available in the
- 942 Supplementary Note.
- 943 VIKING: Supported by a MRC Human Genetics Unit quinquennial programme grant "QTL in Health
- 944 and Disease". VIKING DNA extractions and genotyping were performed at the Edinburgh Clinical
- 945 Research Facility, University of Edinburgh.
- 946 pQTL: The INTERVAL study: NHSBT (11-01-GEN) and the NIHR-BTRU in Donor Health and Genomics
- 947 (NIHR BTRU-2014-10024) at the University of Cambridge in partnership with NHSBT. This study was
- 948 partially funded by Merck. The views expressed are those of the authors and not necessarily those of
- the NHS, the NIHR, the Department of Health of England, or NHSBT. The Cardiovascular
- 950 Epidemiology Unit at the University of Cambridge: UK MRC (G0800270), BHF (SP/09/002), UK NIHR
- 951 Cambridge Biomedical Research Centre, ERC (268834), and European Commission Framework
- 952 Programme 7 (HEALTH-F2-2012-279233)

Author contributions:

- All authors critically reviewed the manuscript prior to submission.
- Contributed to the conception and design of the study: K.S., U.S.S.G., S.K., S.M.K., T.L., P.S.B., T.H.B.,
- 956 E.R.B., Y.B., Z.C., J.D.C., J.D., D.L.D., C.G., A.G., K.H., J.D.H., J.Hokanson, P.J., C.L., L.Li, N.L., J.C.M.,

970 **Competing Interests**

- 971 The following authors report potential competing interests:
- 972 L.V.W.: Louise V. Wain has received grant support from GSK.
- 973 M.D.T.: Martin D. Tobin has received grant support from GSK.
- 974 I.P.H.: Ian P. Hall has received support from GSK and BI.
- 975 K.S.: Kijoung Song is an employee of GlaxoSmithKline and may own company stock.
- 976 J.D.: John Danesh reports personal fees and non-financial support from Merck Sharp & Dohme
- 977 (MSD) and Novartis, and grants from British Heart Foundation, European Research Council, MSD,
- 978 NIHR, NHS Blood and Transplant, Novartis, Pfizer, UK MRC, Wellcome Trust, and AstraZeneca.
- 979 J.D.H.: Josh D. Hoffman is an employee of GlaxoSmithKline and may own company stock.
- 980 N.L.: Nick Locantore is an employee of GlaxoSmithKline and may own company stock.
- 981 J.C.M.: Joseph. C. Maranville was a Merck employee during this study, and is now a Celgene
- 982 employee.
- 983 H.R.: Heiko Runz was a Merck employee during this study, and is now a Biogen employee.
- 984 R. T-S.: Ruth Tal-Singer is an employee of GlaxoSmithKline and owns company stock.
- 985 J.C.W.: John C. Whittaker is an employee of GlaxoSmithKline and may own company stock.
- 986 L.M.Y.: Laura M. Yerges Armstrong is an employee of GlaxoSmithKline and may own company stock.
- 987 E.K.S.: In the past three years, Edwin K. Silverman received honoraria from Novartis for Continuing
- 988 Medical Education Seminars and grant and travel support from GlaxoSmithKline
- 989 A.S.B.: Adam S. Butterworth reports grants from Merck, Pfizer, Novartis, Biogen and Bioverativ and
- 990 personal fees from Novartis
- 991 R.A.S.: Robert A. Scott is an employee of GlaxoSmithKline and may own company stock.
- 992 M.H.C.: Michael H. Cho has received grant support from GSK.

993 **Data availability statement**

- 994 SpiroMeta GWAS summary statistics, UK Biobank GWAS summary statistics and single-variant
- 995 PheWAS results are available by request to the corresponding authors. UK Biobank GWAS summary
- 996 statistics will also be available via UK Biobank (http://www.ukbiobank.ac.uk/). The newly derived
- 997 spirometry quality control variables are available from UK Biobank.

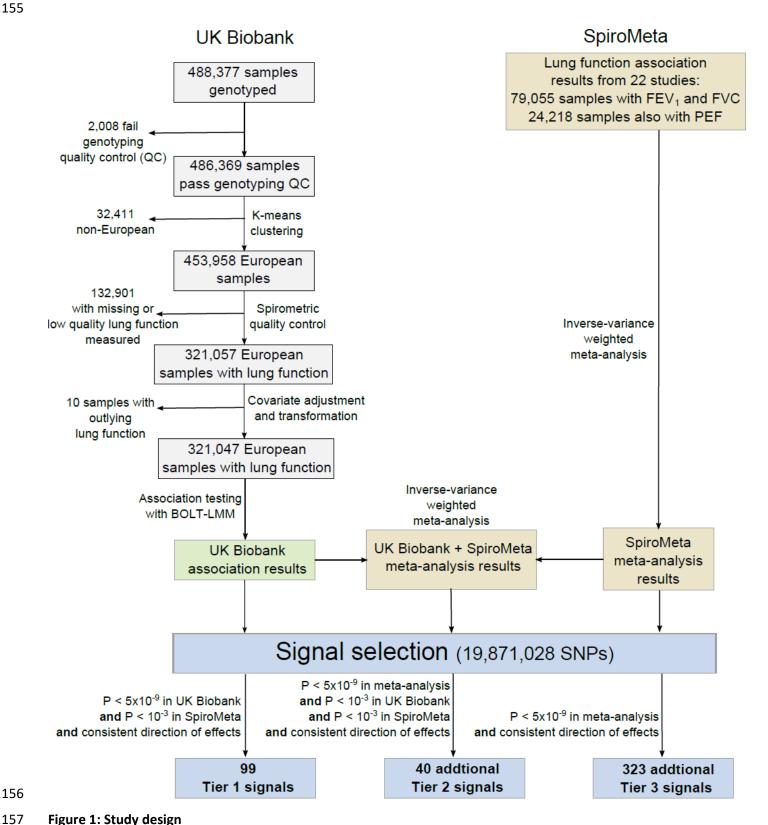

Figure 1: Study design

Tier 1 signals had P<5×10⁻⁹ in UK Biobank and P<10⁻³ in SpiroMeta with consistent direction of effect. Tier 2 signals had P<5×10⁻⁹ in the meta-analysis of UK Biobank and SpiroMeta with P<10⁻³ in UK Biobank and P<10⁻³ in SpiroMeta with consistent directions of effect. Signals with P<5×10⁻⁹ in the meta-analysis of UK Biobank and SpiroMeta, and that had consistent directions of effect but did not meet P<10⁻³ in both cohorts were reported as Tier 3.

158

159

160

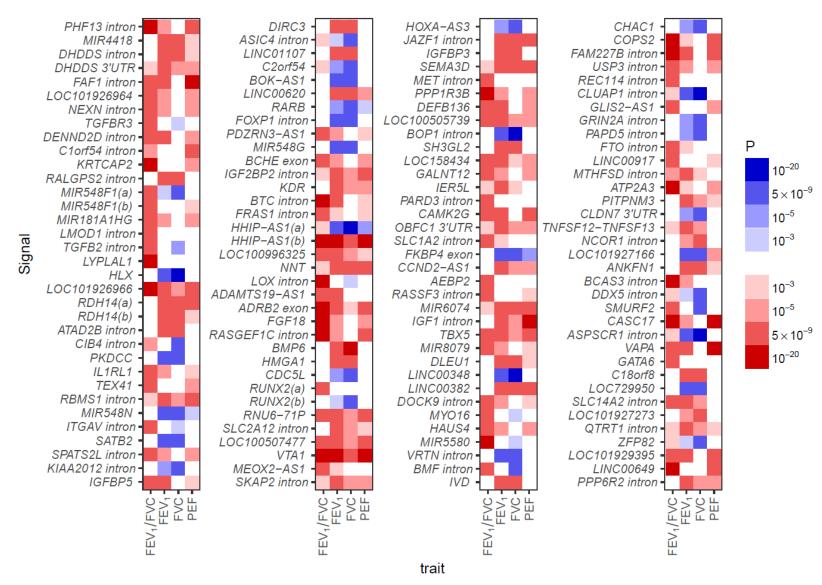

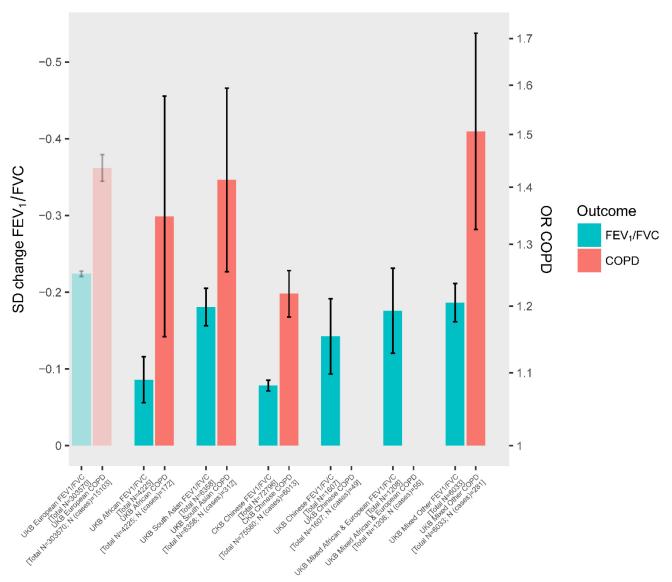

Figure 2: Strength and direction of association across four lung function traits for 139 novel signals: Signals are in chromosome and genomic position order from top to bottom then left to right. Red indicates a decrease in the lung function trait; blue indicates an increase. All effects are aligned to the allele associated with decreased FEV₁/FVC, hence the FEV₁/FVC column is only red or white. P-values are from the meta-analysis of UK Biobank and SpiroMeta (n=400,102). The scale points are thresholds used for (i) confirmation in 2-stage analysis and 1-stage analysis ($P<10^{-3}$); (ii) confirmation of association of previous signals ($P<10^{-5}$); (iii) signal selection in 2-stage and 1-stage analysis ($P<10^{-20}$).

Ancestral group and phenotype studied in UK Biobank or China Kadoorie Biobank

Figure 3: Association of weighted genetic risk score (GRS) with COPD and FEV₁/FVC.

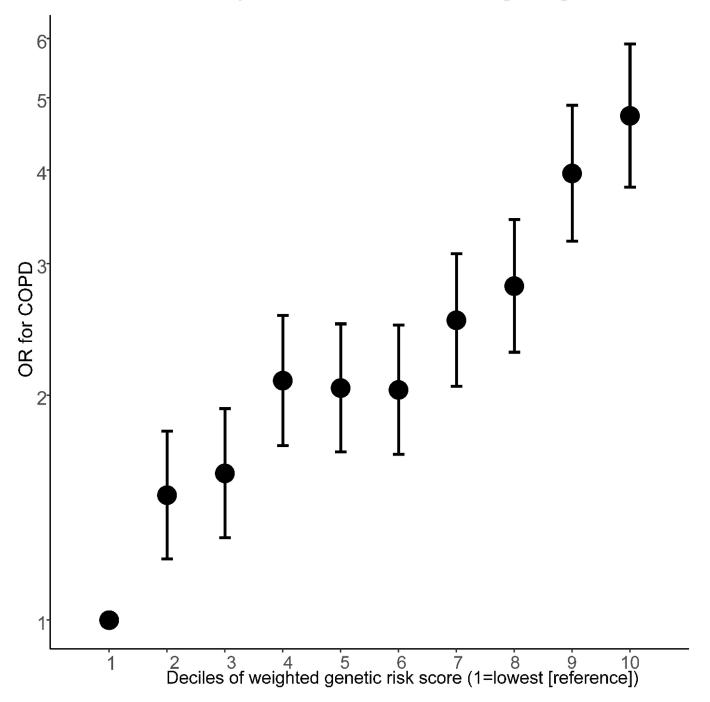

A. Association of the weighted genetic risk score (GRS) with FEV₁/FVC and COPD in UK Biobank and China Kadoorie Biobank (CKB). For means and standard deviations of the risk scores in each group, see Supplementary Table 19. The left-hand axis denotes change in standard deviation (SD) units of FEV₁/FVC per 1 SD increase in weighted GRS (blue bars). The right axis shows the translation of this effect to COPD in the same individuals, defined as FEV₁/FVC<0.7 and FEV₁<0.8 of the predicted value, i.e. GOLD stage 2-4 categorisation. Odds ratios (OR) for COPD (red bars) are given per 1 standard deviation (SD) increase in weighted GRS (OR for COPD shown only for ancestries in UK Biobank with>100 cases of COPD). Bars are labelled with ancestral groups, and the total sample size and number of COPD cases are given. The height of the bars represents the effect estimate, and the black whiskers represent 95% confidence intervals. Note some variants included in the GRS were discovered in UK Biobank individuals of European ancestry, and therefore the results for UKB Europeans (far left bars, greyed out) are shown for reference only. All other ancestral groups shown in the plot are independent to UK Biobank Europeans. There were 13 SNPs with MAF<0.1% in at least one ancestral group: 13/279 in Chinese (of which 4/13 were monomorphic). Two of the 13 SNPs that were monomorphic in Chinese people had MAF<0.1% in Africans.

Weighted risk score associations with COPD susceptibility in COPD case-control studies

Ancestry	Cohort	OR 9	5%LCI 9	5%UCI	Р (Cases	Controls	
European	COPDGene (EUR) ECLIPSE GenKOLS NETT-NAS	1.54 1.59 1.62 1.46	1.31 1.44	1.63 1.91 1.83 1.75	1.97x10 ⁻⁴¹ 1.42x10 ⁻⁰⁶ 8.99x10 ⁻¹⁵ 3.13x10 ⁻⁰⁵	3068 1713 836 374	2110 147 692 429	- - -
	SPIROMICS	1.54	1.38	1.72	4.47x10 ⁻¹⁴	988	537	
	Meta-analysis	1.55	1.48	1.62	1.48x10 ⁻⁷	5 6979	3915	•
African	COPDGene (AFR)	1.26	1.15	1.37	8.36x10 ⁻⁰⁷	910	1556	0.80 1 1.25 1.5 1.75 2 COPD OR per SD increase in risk score

 B. Odds ratio (OR) for COPD per 1 standard deviation (SD) increase in weighted genetic risk score in each of six study groups (COPDGene [Non-Hispanic White], COPDGene [African-American], ECLIPSE, GenKOLS, SPIROMICS, NETT-NAS). COPD was defined using GOLD 2-4 criteria. For means and standard deviations of the risk scores in each group see **Supplementary Table 21**. The vertical black line indicates the null effect (an OR of 1). The point estimate of each study is represented by a box proportional to the study's weight, with the lines representing the lower and upper bounds of the 95% confidence interval. A fixed effect meta-analysis of the five European-ancestry groups is denoted with a diamond, the width of which represents the 95% confidence interval for the estimate (I² statistic=0).

Odds ratio of COPD per decile increase in the weighted genetic risk score

C. Odds ratios (OR) for COPD according to membership of deciles 2-10 of the weighted genetic risk score, with decile 1 as the reference group (the 10% of individuals with the lowest genetic risk score). Each point represents a meta-analysis of results for a given comparison (i.e. decile 2 vs reference, decile 3 vs reference ... decile 10 versus reference) in five external European-ancestry study groups (COPDGene, ECLIPSE, GenKOLS, SPIROMICS, NETT-NAS). Deciles were calculated and models were run in each group separately. Points represent odds ratios, and error bars correspond to 95% confidence intervals (Supplementary Table 22).

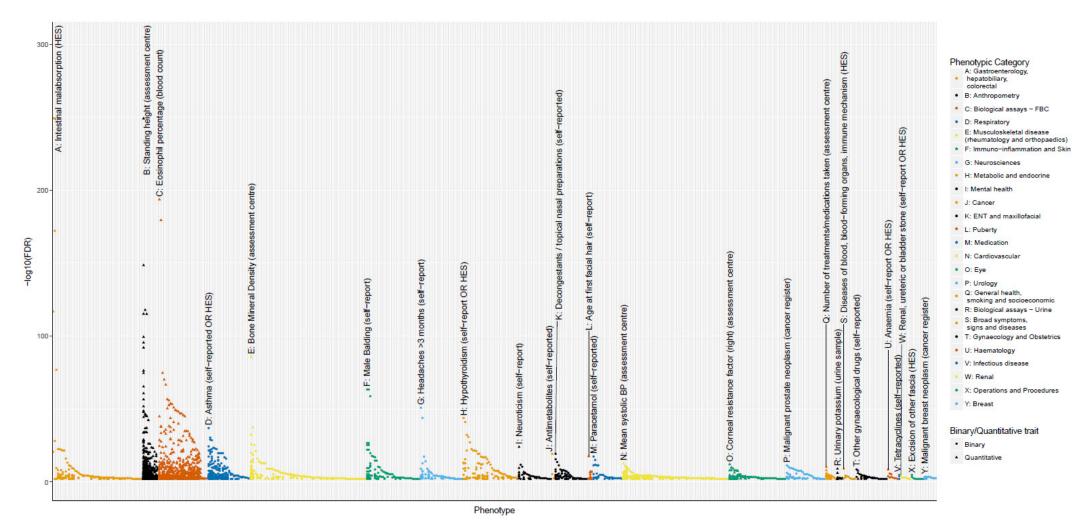

Figure 4: Individual PheWAS with 279 variants (traits passing FDR 1% threshold)

Separate association of 279 variants with 2,411 traits (FDR<1%) in UK Biobank (n up to 379,337). In each category, the trait with the strongest association, i.e. highest – $log_{10}(FDR)$, is shown first, followed by other traits in that category in descending order of $-log_{10}(FDR)$. Categories are colour-coded, and outcomes are denoted with a circular or triangular point, according to whether they were coded as binary or quantitative. The top association per-category is labelled with its rsID number, and a plain English label describing the trait. The letter at the beginning of each label allows easy cross-reference with the categories labelled in the legend. Zoomed in versions of each category with visible trait names and directionality are available in **Supplementary Figure 10**. These plots have signed $log_{10}(FDR)$ values, where a positive values indicates

that a positive SNP-trait association is concordant with the risk allele for reduced lung function (as measured by lower FEV₁/FVC). Tabulated results of all SNP-trait PheWAS associations associated at an FDR of <1% are available in **Supplementary Table 23**.

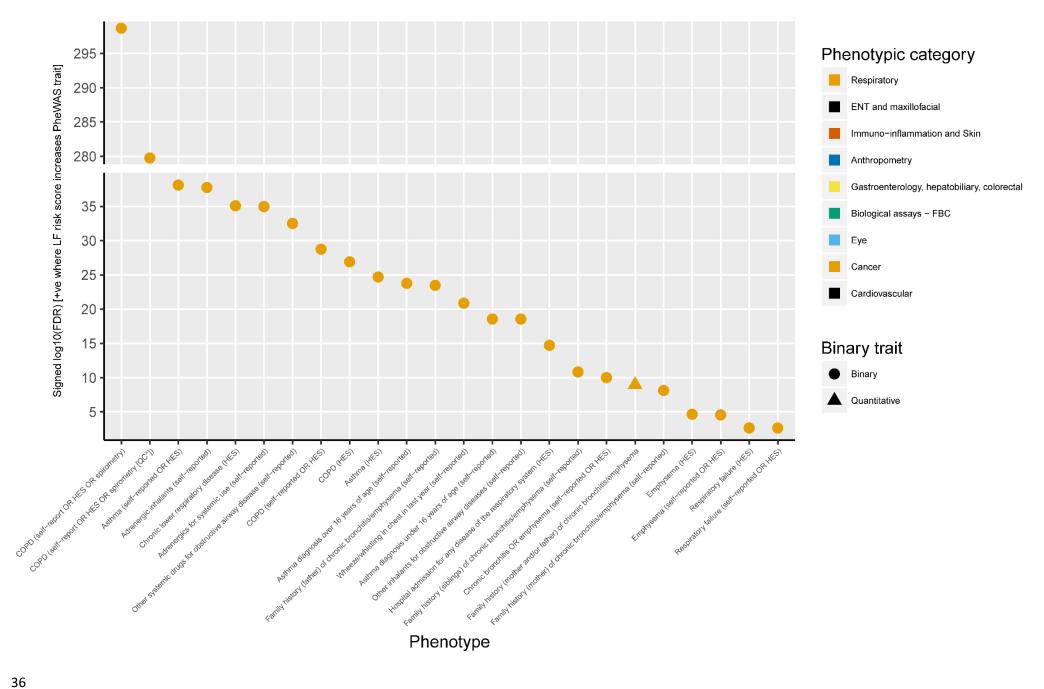

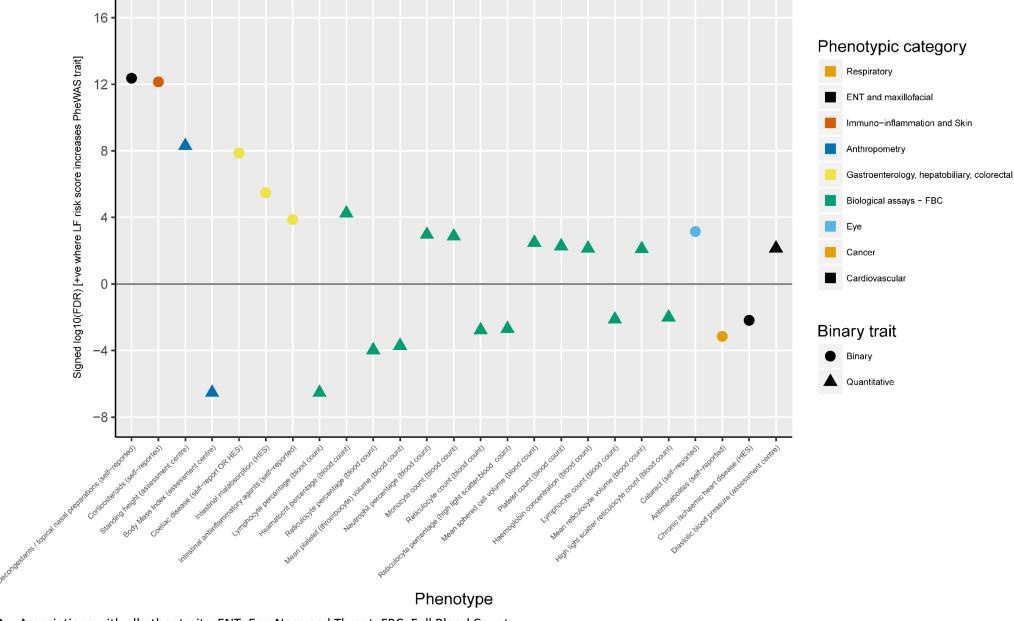

Figure 5: PheWAS with genetic risk score (traits passing FDR 1% threshold)

Association of 279 variant weighted genetic risk score with 2,453 traits (FDR<1%) in UK Biobank (n up to 379,337). In each panel, the category with the strongest association, i.e. highest $-\log_{10}(\text{FDR})$, is shown first, followed by all other associations in that category, ordered by descending order of $-\log_{10}(\text{FDR})$. Sample sizes varied across traits and are available in **Supplementary Table 25**, along with the full summary statistics for each association, plus details of categorisation and plain English labels for each trait. Trait categories are colour coded, and outcomes are denoted with a circular or triangular point, according to whether they were coded as binary or quantitative. The sign of the $\log_{10}(\text{FDR})$ value is positive where an increase in the risk score (i.e. greater risk of COPD, reduced lung function) is associated with a positive effect estimate for that trait. *QC refers to spirometry passing ERS/ATS criteria. HES=Hospital Episode Statistics.

A. Associations with respiratory traits.

B. Associations with all other traits. ENT=Ear, Nose and Throat; FBC=Full Blood Count.

Tables

Table 1: Genes implicated using gene expression data, protein level data and functional annotation

†Genes implicated by eQTL signals: Lung eQTL (n=1,111) and Blood eQTL (n=4,896) datasets and eleven GTEx (V7) tissues were screened: Artery Aorta (n=267), Artery Coronary (n=152), Artery Tibial (n=388), Colon Sigmoid (n=203), Colon Transverse (n=246), Esophagus Gastroesophageal Junction (n=213), Esophagus Muscularis (n=335), Lung (n=383), Small Intestine Terminal Ileum (n=122), Stomach (n=237), and Whole Blood (n=369); see **Supplementary Table 13** for direction of gene expression for the COPD risk (FEV₁/FVC reducing) allele.

- ‡Genes implicated by pQTL signals: pQLT look up in 3,600 plasma proteins (n up to 3,300).
- *Genes implicated because they contain a deleterious variant (Supplementary Table 11).

"Other traits" column lists the other lung function traits for which the sentinel was associated at P<5×10⁻⁹ in the meta-analysis of UK Biobank and SpiroMeta. In total, 107 putative causal genes were identified: 8 by both a deleterious variant and an eQTL signal (including *KIAA0753* implicated by two deleterious variants), 1 (*NPNT*) by both an eQTL and a pQTL signal, 1 (*SCARF2*) by both a deleterious variant and a pQTL signal, 13 by a deleterious variant only, 81 by an eQTL signal only and 3 by a pQTL signal only
